---

# End of Life Scenarios for Bioplastics

Dr John Williams

Head of Polymers & Materials

23<sup>rd</sup> April 2009

NNFCC

## Content

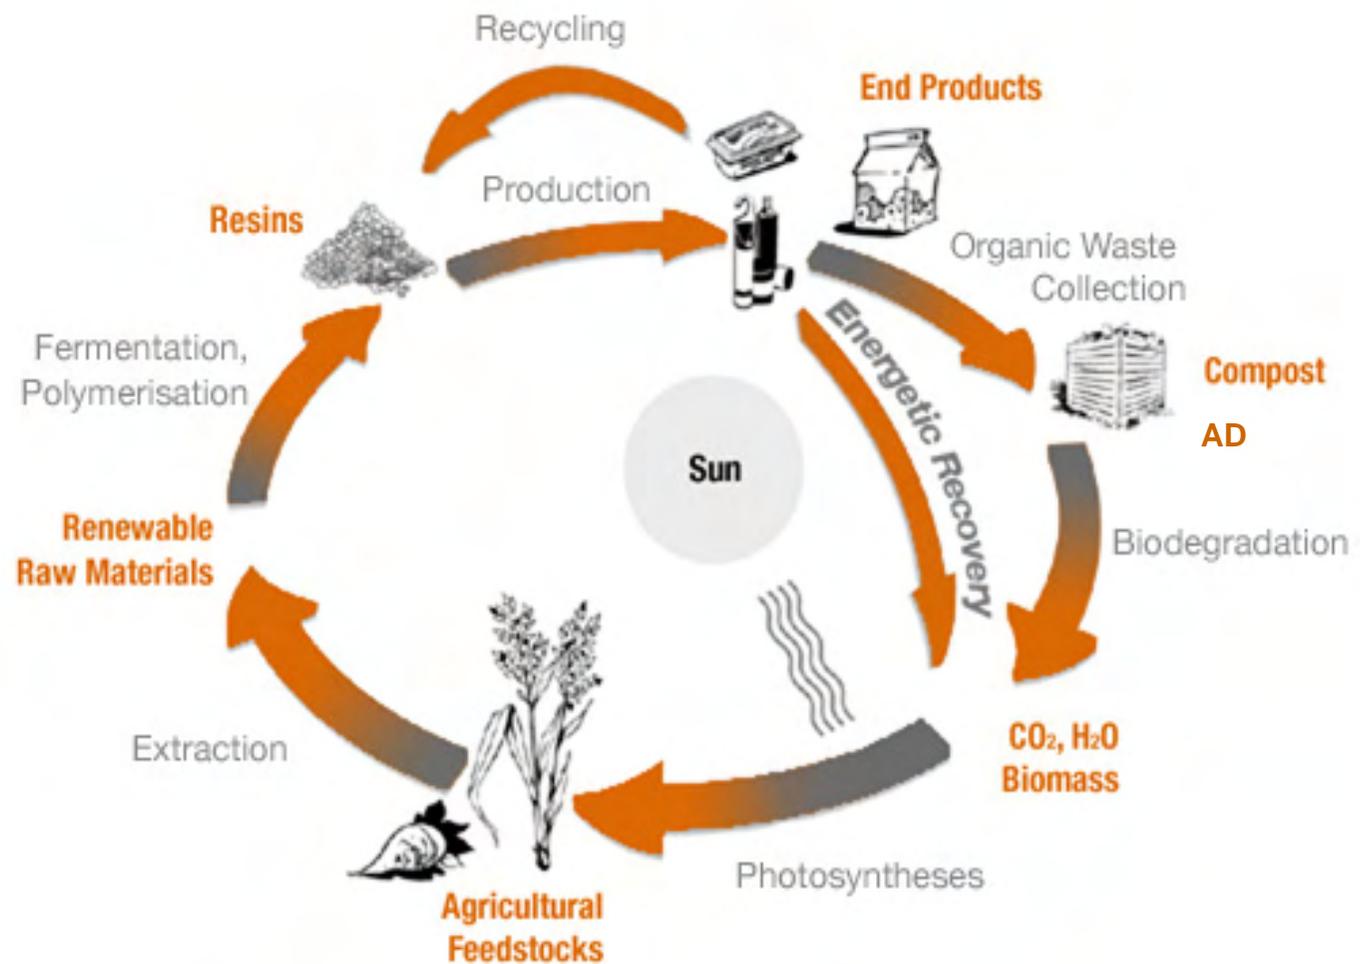

---

- **The key challenges for our world**
- **A circular economy as part of the solution**
- **Waste policies for a circular economy**
- **The role of compostable materials**
- **Conclusions**

NNFCC

# Idealised Closed Loop

Courtesy European Bioplastics

NNFCC

# The Circular Economy

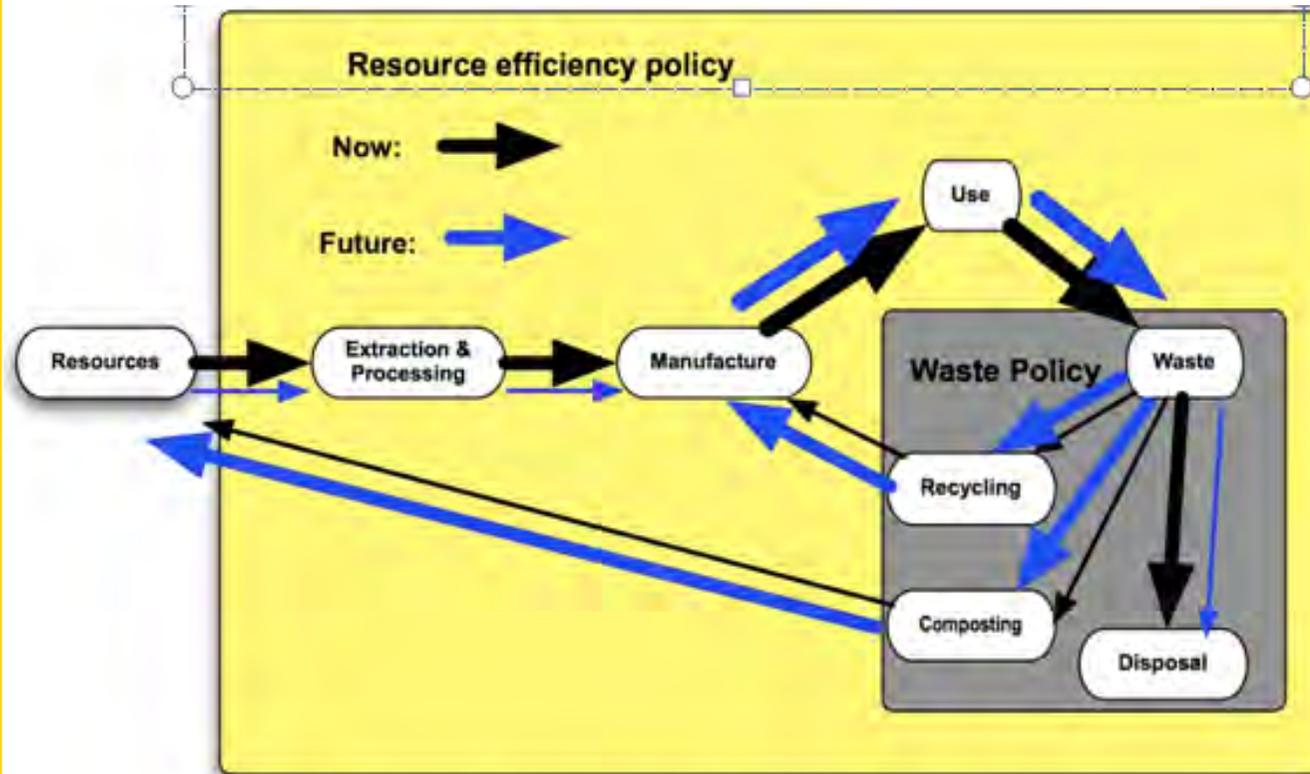

---

- **An economy where ‘waste’ does not exist, with ‘end of life’ resources re-entering the economy**
- **An approach focussed on maximising resource efficiency**
- **Waste policy is a key component of such an approach**
- **A simplified diagram:**

NNFCC

# Waste Policy v Resource Efficiency

NB: There will of course be waste from extraction and processing and manufacturing; this waste is placed at the end of the system in order to simplify the diagram

# Waste Policies to Maximise Resource Efficiency

---

- **The top of the waste hierarchy shows the way:**
  - Waste prevention - the best environmental option, avoiding resource use
  - Reuse - reduces need for resources and manufacturing
  - Recycling - reduces need for extraction and processing of new resources
  - Composting - returns nutrients and structure to soils; displaces other fertilizers; sequesters carbon; and, in the case of anaerobic digestion (AD), produces methane which can be used as a 100% renewable energy source.
- **Then we must phase out the rest - the residual waste, which is currently landfilled or incinerated**

NNFCC

# Mechanical Recycling

<b>Strengths</b> <ul style="list-style-type: none"><li>▪ High purity recyclate</li><li>▪ Simple process</li><li>▪ Value of polymer synthesis preserved</li><li>▪ Outlets for downgraded product</li><li>▪ Techniques for using recycled plastic in demanding applications</li></ul>	<b>Weaknesses</b> <ul style="list-style-type: none"><li>▪ Hard to apply to post consumer waste</li><li>▪ Capital and labour intensive</li><li>▪ Requires clean, homogenous waste streams</li></ul>
<b>Opportunities</b> <ul style="list-style-type: none"><li>▪ Recycle from manufacturing scrap</li><li>▪ Recycle from secondary and tertiary packaging in supply chain</li></ul>	<b>Threats</b> <ul style="list-style-type: none"><li>▪ Biopolymers may be seen as a contaminant to more established materials</li></ul>

NNFCC

# Chemical Recycling

<b>Strengths</b> <ul style="list-style-type: none"><li>▪ Produces a feedstock that can be used to create virgin polymer</li><li>▪ Relies on well established chemical engineering</li><li>▪ Will tolerate greater feedstock variability</li><li>▪ More tolerant to contaminants</li></ul>	<b>Weaknesses</b> <ul style="list-style-type: none"><li>▪ Capital intensive</li><li>▪ Needs a large plant to be cost effective</li><li>▪ Large scale chemical engineering needed – complex process.</li><li>▪ Never proven at full scale</li><li>▪ Only appropriate for some biopolymers</li></ul>
<b>Opportunities</b> <ul style="list-style-type: none"><li>▪ Could handle post-consumer waste</li><li>▪ Could handle multi-material 'engineered' packaging</li><li>▪ Integrate biopolymers with general polymer waste stream</li></ul>	<b>Threats</b> <ul style="list-style-type: none"><li>▪ Energy and transportation costs mean that process will never be viable</li><li>▪ Viable plants cannot handle enough feedstock variability to tackle post consumer waste</li></ul>

NNFCC

# Incineration

<b>Strengths</b> <ul style="list-style-type: none"><li>▪ Handles all waste with a high carbon content</li><li>▪ Recovers energy from original fossil feedstock</li><li>▪ Carbon from biopolymers returned to the biosphere</li><li>▪ Efficient use of resources</li></ul>	<b>Weaknesses</b> <ul style="list-style-type: none"><li>▪ Capital intensive</li><li>▪ Pollution risk if poorly designed or operated</li><li>▪ Public suspicion fuelled by campaigns</li><li>▪ Swings in energy price could threaten viability</li></ul>
<b>Opportunities</b> <ul style="list-style-type: none"><li>▪ Biopolymers contribute to renewable energy</li></ul>	<b>Threats</b> <ul style="list-style-type: none"><li>▪ Public opinion blocks incineration</li></ul>

NNFCC

# Composting

<b>Strengths</b> <ul style="list-style-type: none"><li>▪ Dramatically reduces landfill</li><li>▪ Can cope with any biodegradable material</li><li>▪ Produces a commercial product</li><li>▪ Low energy input</li><li>▪ Returns carbon from biopolymers to the biosphere</li></ul>	<b>Weaknesses</b> <ul style="list-style-type: none"><li>▪ Requires careful separation of waste streams</li><li>▪ Cannot handle 'engineered' packaging that includes non-biodegradable polymers</li><li>▪ Treatment of kitchen waste requires new closed vessel composting</li></ul>
<b>Opportunities</b> <ul style="list-style-type: none"><li>▪ Niches applications where composting can be guaranteed</li><li>▪ Major switch to compostable packaging</li></ul>	<b>Threats</b> <ul style="list-style-type: none"><li>▪ Inadequate market for the compost</li><li>▪ Retailers won't label materials that will not compost at home</li><li>▪ Misclassification problem raises costs</li></ul>

NNFCC

# Anaerobic Digestion

- **E.g. Greenfinch project in Ludlow, UK**
  - Government assisted
  - Strong public support
- **Recycles 5000 tpa of source-segregated waste into:**
  - Pasteurised fertilizer for local agriculture
  - Biogas, producing electricity & heat (100% renewable)

**[www.greenfinch.co.uk](http://www.greenfinch.co.uk)**
- **Anaerobic digestion of food waste from UK households could generate 0.4% of UK electricity demand [5]**
  - More could be generated if commercial food waste, or agricultural waste, was included.

NNFCC

## Phasing Out Residual Waste

---

- **Ensuring that (eventually) everything can be reused, recycled or composted**
- **Mechanisms:**
  - Provision of collection systems
  - Development of processing capacity and markets
  - Regulations requiring recycling of complex materials
    - Including design for recycling
    - E.g. Waste Electrical & Electronic equipment Directive
  - A move to more recyclable plastics
  - **Expansion of compostable materials**

NNFCC

# The Real World

---

- **The waste industry is conservative, and change takes time**
- **You will not get across-the-board transformation of systems in a short period**
  - due to e.g. lack of resources, long contracts & lifespan of equipment
- **The public has limited capacity and willingness to cope with complex waste systems**
  - Complex systems for consumer plastics sorting won't work
  - Compostability must be clear to the public, with a range of signals (labelling, product type, education etc)
- **Therefore, realistic plans must accept that much will remain the same - but there will be some changes**

NNFCC

# Key Opportunities

---

- **Packaging materials that are hard to recycle due to complexity or lack of markets**
  - E.g. much food packaging material
    - Particularly where will be contaminated by food
    - Key need - compostable laminate systems
  - NOT materials that are recycled - e.g. replacing PET or HDPE in bottles
- **Products that may end up in environment as litter**
  - E.g. Carrier bags, Nappies
- **Products that will never be recyclable**
  - E.g. Nappies
- **Bags for compost systems**

NNFCC

# Criteria

---

- **Feedstock:**

- Sustainably produced (I.e. low/no pesticide inputs, low water use etc)
- Non-GM
- Ideally, a waste rather a food

- **Process:**

- Energy efficient
- Resource efficient (zero waste)
- Green chemistry

- **End product:**

- ideally home compostable, and must meet EU compostability standard
- ideally anaerobically digestible
- free of problematic chemicals, including any which would affect compost quality (including additives)

# Sustainable Polymer/Renewable Polymer – A Working Definition

---

- Any polymer material extracted **DIRECTLY** or produced **INDIRECTLY** from the biomass.
- This idea automatically obviously covers Celluloses, Starches, Proteins etc.
- It also covers Polylactic Acid (PLA) and Polyglyconic Acids (PGA's) produced from naturally occurring monomers
- **But it also includes:**
  - Polyethylene produced from ethene, generated by dehydration of Bio-ethanol and;
  - Polypropylene produced from propene derived from Glycerol.

NNFCC

# Some Key Issues?

---

## ■ Recycling / (Reuse)

- Can the polymer be recycled?
  - E.g. Thermoset (NO) versus Thermoplastic (Yes)
- How pure does the recyclate need to be?
  - With respect to polymer type e.g. PE, PP, PET, PLA PHA.
  - With respect to grade E.g. HDPE, UHDPE, LDPE etc.
- How much effort is needed to ensure any material and/or grade purities necessary for recycling?
- How much infrastructure is needed to facilitate recycling?
- How much effort is needed to allow regeneration of the monomer or conversion to another feedstock e.g. Syn Gas?
- Can we make use of less sorted, or even unsorted, waste?
- **How much does the effort of recycling cost ?**

NNFCC

# Some Key Issues?

- **Biodegradability:** For polymers this seems to be a catch all statement requiring degradation mechanisms involving enzymatic and/or microbial actions.
  - Note this definition does not specify:
    - Aerobic or anaerobic actions
    - Where the degradation is taking place (e.g. In a contrived or natural environment)
    - What the polymer is degrading to, for example; CO<sub>2</sub>, H<sub>2</sub>O, CH<sub>4</sub>, biomass
    - The time scale over which any degradation occurs
- **Consider the Questions:**
  - Is wood biodegradable?
  - Is PLA biodegradable?
  - Is traditional PE biodegradable?
  - Do polymers need to be Biodegradable

NNFCC

## Some Key Issues?

---

- **Compostability:** defined standards now exist e.g. EN13432.
- These standards typically define conditions, time scales as well as some outcomes, and required defined tests to be carried out before a claim can be made.
  - But they are specific to end use products not to polymer materials.
    - i.e. You cannot say PLA is compostable, and you can only claim, for example that 12 $\mu$ m thick PLA film is compostable after appropriate testing.
  - This second point often seems to be missed and compostability and biodegradability get confused.

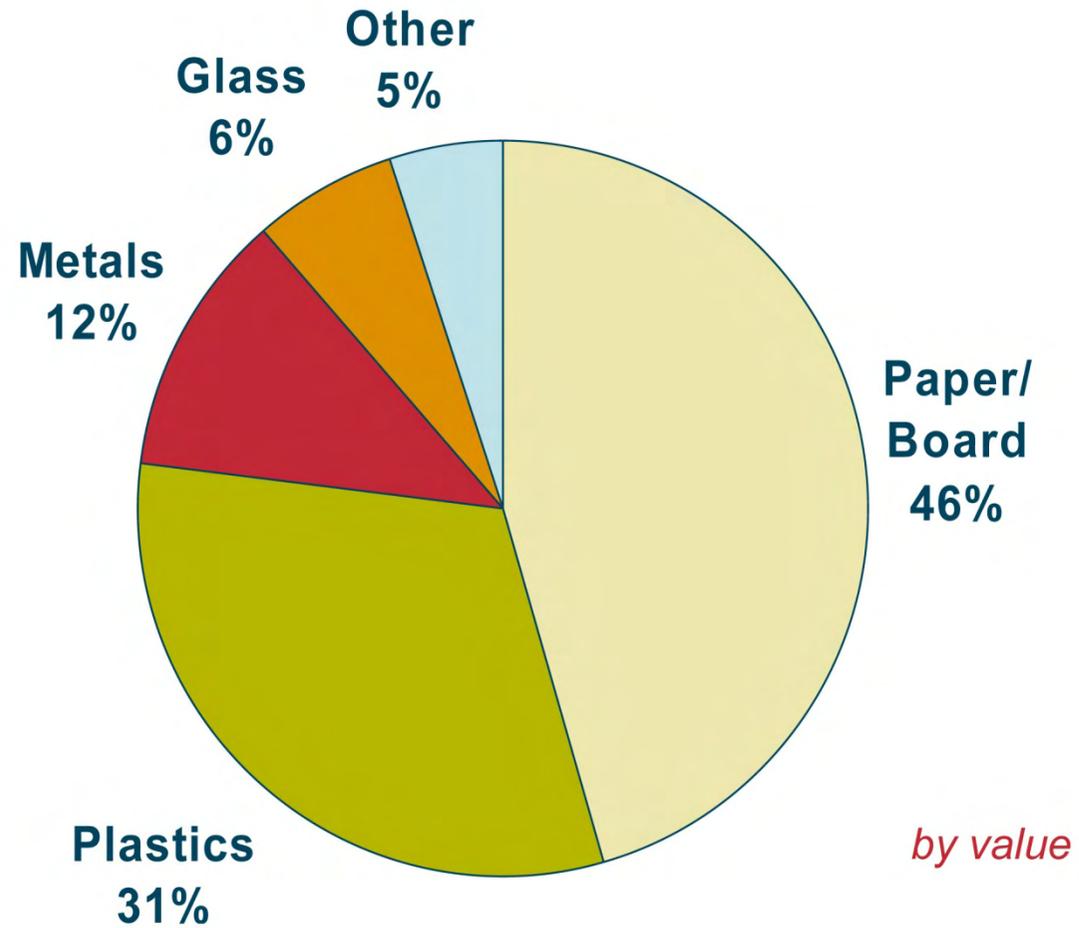

NNFCC

# Packaging Materials

---

NNFCC

# Primary packaging

---

NNFCC

## Secondary packaging

---

NNFCC

# Tertiary packaging

NNFCC

# Renewable Packaging

---

- Drop-in substitutes
- Increasing range of properties
- Meeting real user needs
- Price/performance gap
- Production scale
- Unique properties
- Performance data in use
- Transparent data on life-cycle impact
- Strategy for the use of biomass/waste

NNFCC

## Issues

---

- Renewable *not* biodegradable
- Need for independent advice
- Fragility of public opinion
- Labelling packing as compostable
- ‘Biodegradable’ plastics from petrochemicals
- Overestimating the impact of biopolymers
- Complex ‘engineered’ packaging
- Preparing for success
- Weight based recycling targets
- Incineration as a key part of waste management
- European focus on minimisation and recycling – not renewables

NNFCC

# Conclusions/Opportunities

---

- Exploit interest in renewable polymers
- Learn from paper and board
- Develop the niches for renewable plastics
- Building renewable polymers into eco-design thinking
- Sell benefits of renewable feed-stocks
- Communicate benefits of 'partial' renewable polymers
- Composting & Anaerobic digestion
- Ensure waste management technologies do not exclude biopolymers

NNFCC

## UKRPG

---

- Feedstock – scale-up issues, yields, processing, biorefineries, fermentation
- Polymer manufacture/processing – scale-up forecasts, adhesives, functional coatings
- Packaging – engaging retailers, composting trials, Standards discussion, UKRPG
  - End of Life Options

NNFCC
